

Week 6

Practical Exercises

Strating from the code you wrote for week5 exercises. Modify that code such that:

1. Continuing from the last lab session, create another module record (object of the class "ModuleRecord") for ELEC340. Defined the same students as those in the module ELEC362, give them different marks in ELEC340 than those they got in ELEC362.
2. Implement a standalone function to compute the overall average of a specific student based on their marks in ELE362 and ELEC340.
3. Using the function in step 3, students with mark average less than 40 should be moved into a new container.
4. Use the sort algorithm to sort the students based on their average marks. Hint: Define a function by overloading the () operator, the return datatype of the function should match the object to be sorted (i.e. Student).

To run and test your code, create students' profiles and assign their marks in each module as you wish (no need to consider the user's input since this is an exercise). Use STL algorithms as much as possible in this exercise.
