

Week 5

Practical Exercises

You are working on a software development project to build a software for management of personnel at the university:

1. Create a class called "Person", the information assigned for a person are their Full name and date of birth.
2. From that class, derive a class called "Student" and class called "Staff". For a student the added attributes should be the student number and their average mark, for "Staff" the additional attributes should be the staff ID as well as their income.
3. For a given person, a function to give their full name should be defined.
4. For a given person, a function to give their classification "Student" or "Staff" should be defined.
5. Create another class called "ModuleRecord" to keep a record of all students and staff registered on a module, a student can be added to the module by a line of code like:
`ELEC362 += MohammadHasan;`
The added entry can be a staff or a student.
6. The ModuleRecord class should have a function to list all staff on the module and another function to list all the students registered on the module.

Use STL containers to write this code.

When defining classes, use the two files convention.
